TEAM INITIATORS · DISTRICT IQ REVIEW · 18 OCT 2026, 4:45 PM

Intro script

For [friend's name] · about 5 minutes

About 5 minutes. Speak slowly. No screen needed except the title or architecture slide if you have one. Bold words are the ones to stress.

Opening 0:00 – 0:30

SAY

Good afternoon, everyone. Thank you for your time today.

We are **Team Initiators**. I am [friend's name], and with me is [your name]. Today we are presenting **District IQ**, a district intelligence platform for the **Collector of Chennai**, built for FarmwiseAI's Task 6.

I will explain the problem we chose to solve and how the whole system fits together. After that, [your name] will take you through the live website end to end: how the data is collected, the algorithms behind it, and what the Collector, the department officers and the citizens each see.

The problem 0:30 – 1:30

SAY

A District Collector is responsible for almost everything that happens in the district: floods and rain, roads, drinking water, health, law and order, even vegetable prices.

But the information reaches the Collector from **many separate places**: department systems, newspapers in English and Tamil, IMD weather warnings, the flood monitoring system, air-quality stations, reservoir levels and citizen complaints. Each one has its own website, its own format and its own timing. **None of it is joined up.**

So one waterlogged street can show up as three citizen complaints, a police report, a PWD work order and two news articles, one in Tamil and one in English. Nobody sees that it is **one problem**, and nobody can say which problem needs attention first.

Our solution in one sentence `1:30 – 2:00`

SAY

District IQ brings all of this into one place and answers two questions for the Collector every morning: **What is happening in my district?** And **what needs my attention first, and why?**

What the system does: four ideas `2:00 – 3:15`

SAY

One, it collects automatically. Every hour, our collectors pull data from public sources: news, IMD weather and warnings, CPCB air quality, the Chennai Flood Monitor, Chennai Metro Water lake levels and market prices.

Two, it joins the data. Duplicate reports are merged, and reports of the same event from different sources, and even different languages, are linked into a single **incident**, with a timeline and the evidence behind it.

Three, it prioritises with reasons. Every incident gets a severity and a priority, and the reasons are written out: how serious it is, how many sources report it, whether it is past its deadline, whether vulnerable people are affected. Unusual rises are found with proper statistical tests, so the Collector gets a few real alerts instead of dozens of false ones.

Four, it helps the Collector act. The Collector can send work to the department officer, verify completed work, read a daily briefing, and simply ask questions in English or Tamil. Every number in an answer comes from the data, and every number the AI writes is checked before it is shown.

Who uses it `3:15 – 3:45`

SAY

There are three kinds of users. The **Collector**, who sees the whole district. **Department officers**, 25 departments, each seeing only their own work. And **citizens**, who file complaints and track them. Citizens can sign up themselves; officer and Collector accounts are issued, never self-registered.

The data, stated honestly `3:45 – 4:30`

SAY

We want to be clear about our data.

The **public data is real and live**: about fourteen thousand Chennai news articles in English and Tamil, from The Hindu, Times of India, DT Next, the New Indian Express, Dinamani, Dinamalar and Google News; IMD weather and district warnings; CPCB air quality; the Chennai Flood Monitor's river gauges and reservoirs; Chennai Metro Water's lake levels; and AGMARKNET and farmer-market prices.

The **department records** (grievances, police, PWD and hospitals) are **simulated**, because these departments do not publish open data. We generate realistic records in the same format a real system would send, tied to the real weather and the real wards of Chennai, and every simulated row is flagged. Connecting a real department later means writing one loader. Nothing else in the system changes.

Architecture in one breath `4:30 – 5:00`

SAY

Technically, it is a pipeline. **Collectors** gather the data. A **Python pipeline** cleans it, links it and analyses it every hour on GitHub Actions. The result is stored on **AWS**, in S3 and DynamoDB. The **website**, built with Next.js, reads it from there. The AI runs on **Amazon Bedrock**, with Gemini and Groq as backups, and the site keeps working from the data even when no AI is available.

With that, I will hand over to [your name], who will show you the live system.

> If a reviewer interrupts with a deep technical question, answer in one line and say: "[Your name] will show exactly that in the demo."
